

#7: Weighted Enumerative Search - I

Sankha Narayan Guria

EECS 700: Introduction to Program Synthesis

Scaling enumerative search

Prune

- Discard useless subprograms

$$m * N^2$$

$$m * (N - 1)^2$$

Prioritize

- Explore more promising candidates first

$$P = \{ \begin{array}{l} [0][N..N] \\ x[N..N] \\ \dots \end{array} , \quad \leftarrow \begin{array}{l} \text{dequeue} \\ \text{this first} \end{array}$$

Order of search

- Enumerative search explores programs by depth / size
 - Good default bias: small solution is likely to generalize
 - But far from perfect
- Result:
 - Scales poorly with the size of the smallest solution to a given spec

Top-down search (revisited)

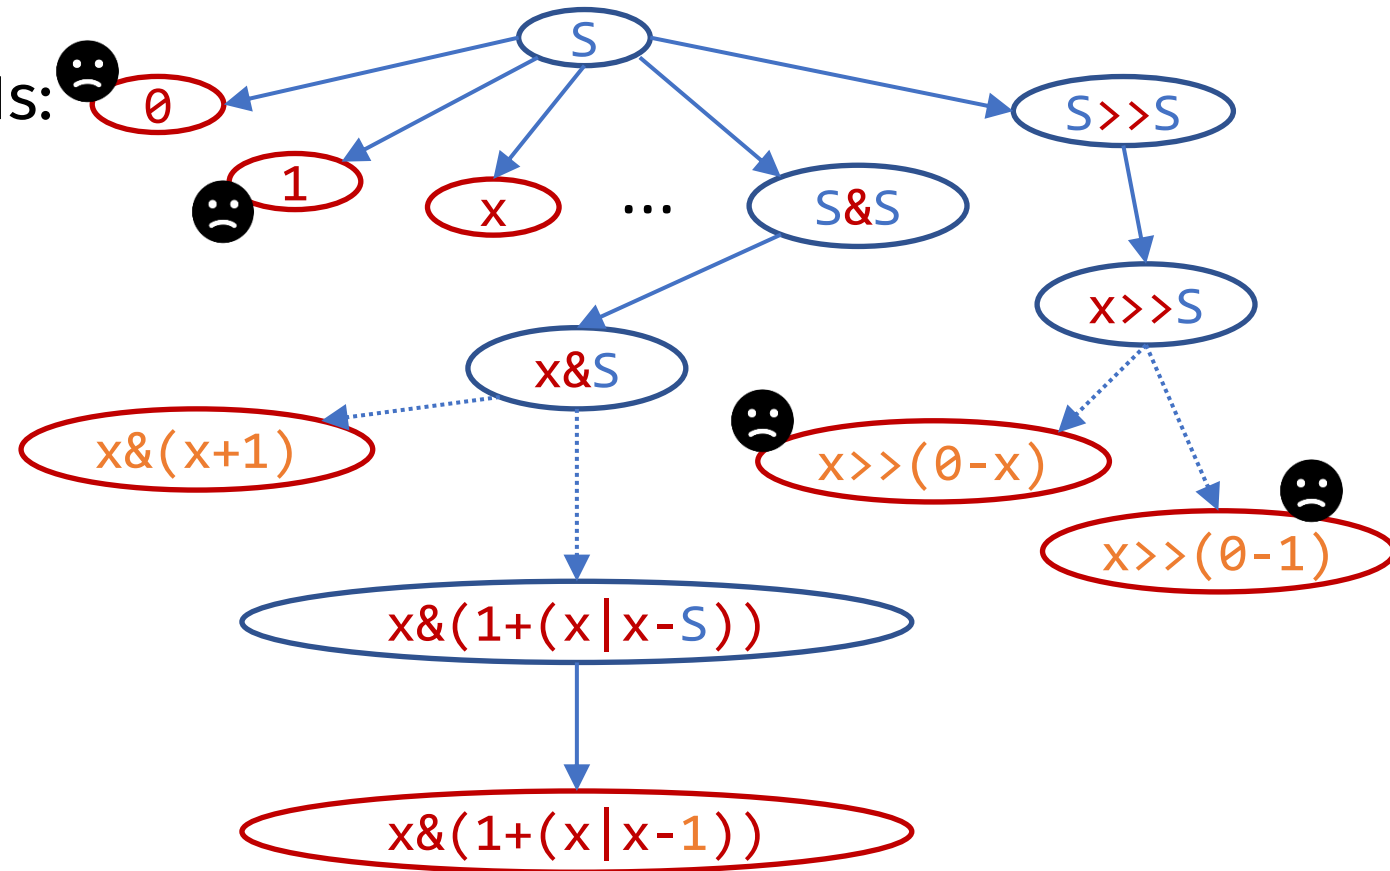

Turn off the rightmost sequence of 1s: ☹️

00101 → 00100

01010 → 01000

10110 → 10000

S	->	0		1		x	
S	+	S					
S	-	S					
S	&	S					
S		S					
S	<<	S					
S	>>	S					

Explores many unlikely programs!

Biasing the search

- **Idea:** explore programs in the order of **likelihood**, not **size**
- **Q1:** how do we know which programs are likely?
 - hard-code domain knowledge
 - learn from a corpus of programs
 - learn on the fly
- **Q2:** how do we use this information to guide search?
 - **our focus today!**

Weighted enumerative search

Example: DeepCoder

Balog et al. DeepCoder: Learning to Write Programs. ICLR'17

Probabilistic Grammars

Weighted top-down search

Weighted bottom-up search

DeepCoder

Input: IO-
examples

```
[-17 -3 4 11 0 -5 -9 13 6 6 -8 11]  
→ [-12 -20 -32 -36 -68]
```

DeepCoder

Output: Program
in a list DSL

```
a <- [int]  
b <- Filter (<0) a  
c <- Map (*4) b  
d <- Sort c  
e <- Reverse d
```

DeepCoder

Input: IO-examples

`[-17 -3 4 11 0 -5 -9 13 6 6 -8 11]`
→ `[-12 -20 -32 -36 -68]`

neural network

weighted search

component weights

(+1)	(-1)	(*2)	(/2)	(*1)	(**2)	(*3)	(/3)	(*4)	(/4)	(>0)	(>0)	(%2==1)	(%2==0)	HEAD	LAST	MAP	FILTER	SORT	REVERSE	TAKE	DROP	ACCESS	ZIPWITH	SCANL1	+	,	*	MIN	MAX	COUNT	MINIMUM	MAXIMUM	SUM
.0	.0	.1	.0	.0	.0	.0	.0	1.0	.0	.0	1.0	.0	.2	.0	.0	1.0	1.0	1.0	.7	.0	.1	.0	.4	.0	.0	.1	.0	.2	.1	.0	.0	.0	.0

Output: Program in a list DSL
Goal: Minimize sum of component weights

DeepCoder: search strategies

- Top-down DFS
 - Picks expansions for the current non-terminal in the order of probability
- Sort-and-add
 - start with N most probable functions
 - when search fails, add next N functions
- Pros and cons?

Recall: goal is to explore programs in the order of total weight!

Weighted enumerative search

DeepCoder

Probabilistic Grammars

Weighted top-down search

Weighted bottom-up search

Probabilistic Language Models

- Originated in Natural Language Processing
- In general: a probability distribution over sentences in a language
 - $P(s)$ for $s \in L$
- In practice:
 - must be in a form that can be used to guide search
 - for enumerative search: **probabilistic** (or **weighted**) **grammars**

Probabilistic (Tree) Grammar

regular tree
grammar

production probability
(given context)

$\langle G, \wp \rangle$

- Production probability: $\wp: R \times T_\Sigma(N) \rightarrow [0,1]$
 - for example: $\wp(S \rightarrow x \mid S) = 0.3$ $\wp(S \rightarrow x \mid x \leftarrow S) = 0.0001$
 - only defined for contexts where rule's LHS is the leftmost non-terminal
 - probabilities of all productions in the same context add up to 1:

$$\forall \tau. S \rightarrow^* \tau \wedge \tau \notin T_\Sigma \Rightarrow \sum_{r \in \text{dom}(P(\cdot \mid \tau))} P(r \mid \tau) = 1$$

- Term probability:
 - let $S = \tau_0 \xrightarrow{r_1} \tau_1 \xrightarrow{r_2} \dots \xrightarrow{r_n} \tau_n = \tau$ be the unique derivation of partial program τ

$$\wp(\tau) = \prod_{i=1}^n \wp(r_i \mid \tau_i)$$

Types of context

$$\varphi: \mathbb{R} \times T_{\Sigma}(N) \rightarrow [0,1]$$

- In general, can depend on any part of the context term!
- But this is unwieldy
 - bad for learning
 - bad for (some) search algorithms
- In practice we want to restrict the context
 - PCFG
 - n-grams
 - PHOG

Probabilistic Context-Free Grammars (PCFG)

	$\wp(R)$
$S \rightarrow \emptyset$	0.13
$S \rightarrow 1$	0.13
$S \rightarrow x$	0.18
$S \rightarrow S + S$	0.11
$S \rightarrow S - S$	0.11
$S \rightarrow S \& S$	0.12
$S \rightarrow S S$	0.12
$S \rightarrow S \ll S$	0.05
$S \rightarrow S \gg S$	0.05

$$\wp: R \rightarrow [0,1]$$

- Encodes the popularity of each production (operation)
 - here: variable more likely than constant, plus more likely than shift

Probabilistic Context-Free Grammars (PCFG)

$S \rightarrow \theta$	$\wp(R)$
$S \rightarrow 1$	0.13
$S \rightarrow x$	0.13
$S \rightarrow S + S$	0.18
$S \rightarrow S - S$	0.11
$S \rightarrow S \& S$	0.11
$S \rightarrow S S$	0.12
$S \rightarrow S \ll S$	0.12
$S \rightarrow S \gg S$	0.05
	0.05

N-grams

`N[left sibling, parent] -> rhs`

		\emptyset	
<code>S[x, -]</code>	<code>-></code>	<code>1</code>	0.72
<code>S[x, -]</code>	<code>-></code>	<code>x</code>	0.02
<code>S[x, -]</code>	<code>-></code>	<code>S + S</code>	0.12
<code>S[x, -]</code>	<code>-></code>	<code>S - S</code>	0.12
...			
<code>S[1, +]</code>	<code>-></code>	<code>1</code>	0.26
<code>S[1, +]</code>	<code>-></code>	<code>x</code>	0.25
<code>S[1, +]</code>	<code>-></code>	<code>S + S</code>	0.19
<code>S[1, +]</code>	<code>-></code>	<code>S - S</code>	0.08

- Encodes likelihood of a production in a **fixed context**

- fixed set of AST nodes determined relative to the focus nonterminal
- e.g. left sibling and parent

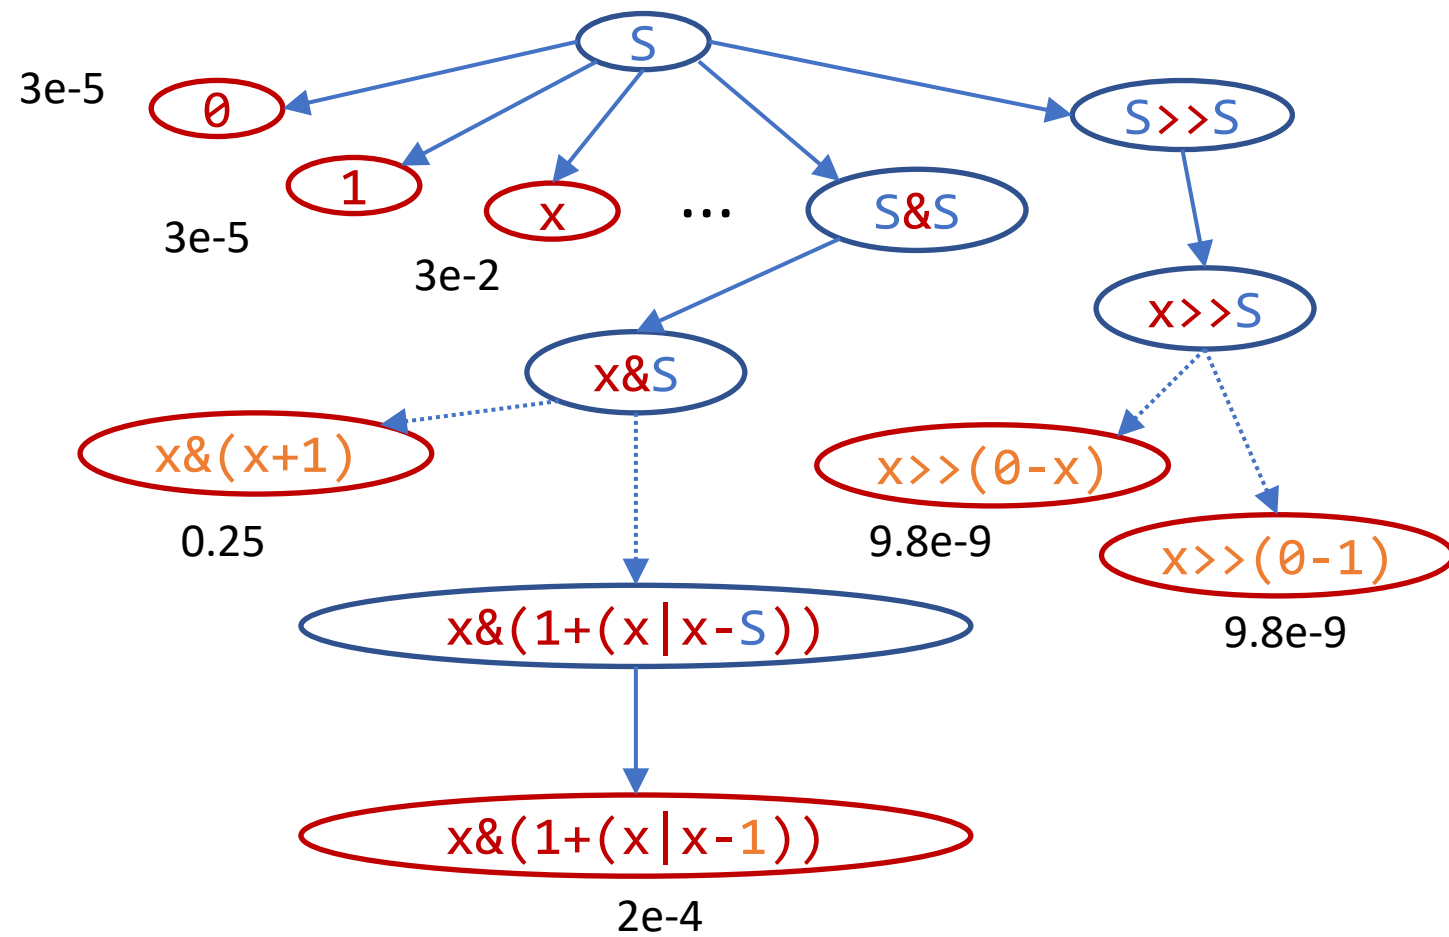

- here: x is not likely in `x - S`?
but likely in `1 + S`?

N-grams

$N[\text{left sibling, parent}] \rightarrow \text{rhs}$

		ϕ
$S[x, -] \rightarrow$	1	0.72
$S[x, -] \rightarrow$	x	0.02
$S[x, -] \rightarrow$	$S + S$	0.12
$S[x, -] \rightarrow$	$S - S$	0.12
...		
$S[1, +] \rightarrow$	1	0.26
$S[1, +] \rightarrow$	x	0.25
$S[1, +] \rightarrow$	$S + S$	0.19
$S[1, +] \rightarrow$	$S - S$	0.08

Probabilistic Higher-Order Grammar (PHOG)

- The same fixed context might not work for every problem
- Idea:
 1. 1. define context as a program that traverses the AST
 2. 2. learn the best context together with probabilities

Bielik, Raychev, Vechev. [PHOG: Probabilistic Model for Code](#). ICML'16

Conditional models

- **Unconditional model**

- Which programs are more natural in this DSL?

- + easier to get data / learn
- need more context to capture interesting properties

- **Conditional model**

- Which programs are more likely to solve **a given spec**?

- harder to get data / learn
- can get away with less context
